

# A Bridge to Equality: How Investing in Infrastructure Affects the Distribution of Wealth

John Gibson<sup>1</sup> Felix Rioja<sup>2</sup>

Georgia State University

November 22, 2014

# Motivation

## **How does investing in infrastructure affect the distribution of wealth in a country?**

- Could reduce inequality by boosting wages
- Could increase inequality by boosting interest rates
- Testing this requires a quantitative model

## **Infrastructure affects individual choice through many channels**

- We consider two: production and utility
- Understanding which channel drives results is important

# Literature

## Infrastructure Investment and Growth:

- Empirical literature generally finds a positive effect of infrastructure on economic growth
  - Aschauer (1989), Bom and Ligthart (2009) and Romp and Den Haan (2007)
- Theoretical literature supports this finding
  - Barro (1990), Glomm and Ravikumar (1994) and Rioja (1999, 2003)

## Common Consensus: Infrastructure increases growth

# Literature

## Infrastructure Investment and Inequality:

- Empirical literature finds mixed results:
  - Reduce Inequality: Calderon and Severn (2004), Calderon and Chong (2004)
  - Increase Inequality: Khandker and Koolwal (2010) and Artadi and Sala-i-Martin (2004)
- Theoretical literature also finds mixed results:
  - No Effect: Glomm and Ravikumar (1994b)
  - Reduce Inequality: Ferreira (1995) and Klenert et al (2014)
  - Increase Inequality: Chatterjee and Turnovsky (2012)

## No common consensus on infrastructure and inequality

## Our Contribution

### **Modify Aiyagari (1994) to include:**

- Endogenous labor supply decision
- Infrastructure impacts both production and utility

### **Our modeling strategy allows us to:**

- Focus on ex post rather than ex ante heterogeneity
- Calibrate our model using income data
- Consider both quantitative as well as qualitative results

**Determine which channel (production or utility) drives the distributional results**

## Preview of Results

### Increase infrastructure investment from 2% to 5% of GDP

- 1 Large effects when both channels are operational
  - Aggregate output increases by 128% on average
  - Wealth concentration **falls by 13.4%** on average
- 2 Small effects when utility channel is shut down
  - Aggregate output increases by 18% on average
  - Wealth concentration **increases by 3%** on average

### Distributional effects transmitted through utility channel

# Model Setup

## Extended version of Aiyagari (1994)

- Agents are ex ante identical
- Idiosyncratic shocks to labor productivity
- Partially insure against shocks by accumulating assets

## Infrastructure affects choices through two channels:

- Production: Affects both output and factor prices
- Utility: Affects total and marginal utility

# Role of Infrastructure

**Infrastructure impacts the economy through the following channels:**

**1** Production

- $Y(K_G, K, N) = K_G^\phi K^\alpha N^{1-\alpha}$
- Infrastructure directly affects output and factor prices

**2** Utility

- $U(c, L) = \frac{1}{\gamma} [c^{-\xi} + \eta L^{-\xi}]^{\frac{\gamma}{\xi}}$
- L denotes effective leisure,  $L = lK_G$
- Infrastructure directly affects marginal utility of leisure

# Household's Problem

$$V(a, \theta) = \max_{c, n, l, a'} \left[ \frac{1}{\gamma} (c^{-\xi} + \eta L^{-\xi})^{-\frac{\gamma}{\xi}} + \beta \sum_{\theta'} \pi(\theta' | \theta) V(a', \theta') \right]$$

s.t.

$$(1 + \tau_c)c + a' \leq \left\{ \begin{array}{ll} (1 + (1 - \tau_a)r)a + (1 - \tau_n)wn\theta & \text{if employed} \\ (1 + (1 - \tau_a)r)a + b & \text{if unemployed} \end{array} \right\}$$

$$n + l \leq 1, a' \geq 0 \text{ and } L = lK_G$$

Solving this yields the following labor supply:

$$n = \frac{1 + \tau_c + \left[ \frac{\eta(1 + \tau_c)}{K_G^\xi (1 - \tau_n) w \theta} \right]^{\frac{1}{1 + \xi}} [g(a, \theta) - (1 + (1 - \tau_a)r)a]}{1 + \tau_c + \left[ \frac{\eta(1 + \tau_c)}{K_G^\xi (1 - \tau_n) w \theta} \right]^{\frac{1}{1 + \xi}} (1 - \tau_n) w \theta}$$

# Household's Problem (without utility channel)

$$V(a, \theta) = \max_{c, n, l, a'} \left[ \frac{1}{\gamma} (c^{-\xi} + \eta l^{-\xi})^{-\frac{\gamma}{\xi}} + \beta \sum_{\theta'} \pi(\theta'|\theta) V(a', \theta') \right]$$

s.t.

$$(1 + \tau_c)c + a' \leq \begin{cases} (1 + (1 - \tau_a)r)a + (1 - \tau_n)wn\theta & \text{if employed} \\ (1 + (1 - \tau_a)r)a + b & \text{if unemployed} \end{cases}$$

$$n + l \leq 1 \text{ and } a' \geq 0$$

Solving this yields the following labor supply:

$$n = \frac{1 + \tau_c + \left[ \frac{\eta(1+\tau_c)}{(1-\tau_n)w\theta} \right]^{\frac{1}{1+\xi}} [g(a, \theta) - (1 + (1 - \tau_a)r)a]}{1 + \tau_c + \left[ \frac{\eta(1+\tau_c)}{(1-\tau_n)w\theta} \right]^{\frac{1}{1+\xi}} (1 - \tau_n)w\theta}$$

# Firm's Problem

## The representative firm solves a standard problem

- Choose aggregate capital,  $K$ , and aggregate labor,  $N$ , to maximize  $\pi$
- $\pi = K_G^\phi K^\alpha N^{1-\alpha} - wN - (r + \delta)K$

## Solving the problem yields standard marginal conditions:

- $r = \alpha K_G^\phi \left(\frac{K}{N}\right)^{\alpha-1} - \delta$
- $w = (1 - \alpha) K_G^\phi \left(\frac{K}{N}\right)^\alpha$

# Government Problem

**The government is assumed to do the following:**

- 1 Invest in infrastructure,  $K_G$ 
  - $\delta_G K_G = x K_G^\phi K^\alpha N^{1-\alpha}$
- 2 Provide unemployment benefits,  $B$ 
  - $B = \int_0^{\bar{a}} b f(a, \theta = 0) da$
- 3 Engage in government consumption,  $G$

**The government is assumed to run a balanced budget**

$$B + \delta_G K_G + G = \tau_c C + \tau_n wN + \tau_a rK$$

# Calibration

## **Model is calibrated to an annual frequency**

- Parameter values taken from literature

## **Income shock process is calibrated using survey data from Mexico**

- Mexico National Institute of Statistics and Geography (INEGI)
- National Survey of Occupation and Employment (ENOE)
- Survey 100,000 households in 48 metropolitan and rural areas in Mexico every year

# Calibration

Table 1: Model Parameters

$\beta = 0.96$	$\eta = 0.75$	$\gamma = -1.50$	$\xi = 1.50$
$\alpha = 0.36$	$\phi = 0.15$	$\delta = 0.06$	$\delta_G = 0.04$

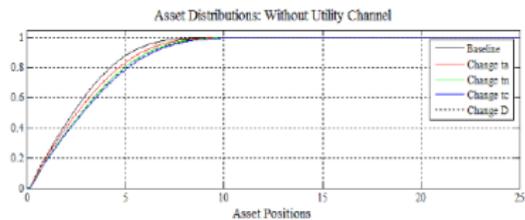

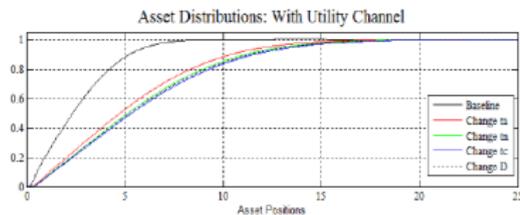

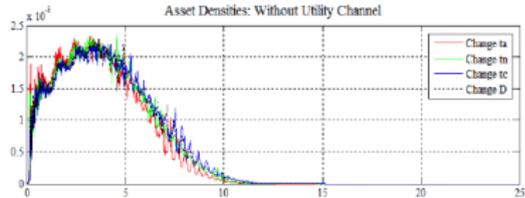

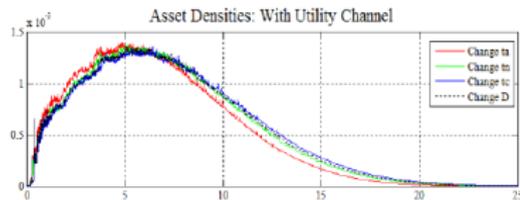

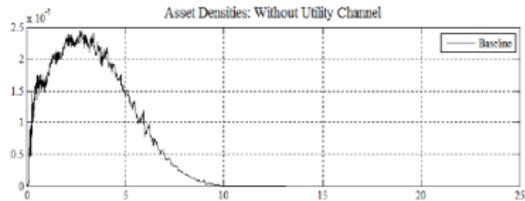

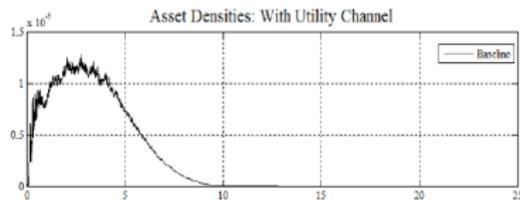

Table 2: Productivity Shock Process

$\theta_1 = 0.000$	$\theta_2 = 0.331$	$\theta_3 = 0.588$	$\theta_4 = 0.878$	$\theta_5 = 2.203$

# Conclusions

## **Investing in infrastructure can increase growth and reduce inequality**

- Wealth share of lower quintiles increases
- Wealth share of higher quintiles falls

## **Choice of financing method does not matter much**

- Interest income tax performs the worst

## **Distributional effects operate through utility channel**

- Wealth distribution barely changes when utility channel is shut down
